Serum Copper and Zinc ratio in Psoriasis

Margit Gajjar¹, H.B.Sirajwala²

¹Tutor, ²Associate Professor, Department of Biochemistry, Medical College, Baroda, Gujarat, India

ABSTRACT
BACKGROUND: Psoriasis is a chronic inflammatory skin disease characterized by well-demarcated erythema and scaly plaques. An increased reactive oxygen species (ROS) and insufficient antioxidant activity associated with the pathogenesis of psoriasis lesions. The aim of study was to evaluate the link between trace elements like zinc (Zn) and copper (Cu) ion ratio with the pathogenesis of psoriasis disease and to evaluate the essential metals in psoriasis in comparison with healthy controls. MATERIAL AND METHODS: Fifty patients with psoriasis were included in this study, 30 patients with severe psoriasis, and 20 with Mild psoriasis, another fifty healthy controls were included in this study. We measured Serum Zn and Serum Cu in patients and age and sex match healthy control subjects. In psoriatic patients the severity of psoriasis was assessed by ‘Psoriasis Area Severity Index’ (PASI score). RESULT: It was also found that in severe Psoriasis (PASI SCORE >10), significantly higher mean Serum Copper/Zinc ratio (2.04±1.04) than with mild (PASI SCORE <10) Psoriasis (1.54±0.71) and controls (1.2±0.3). CONCLUSION: This study demonstrated some disturbances in serum levels of metals in psoriasis. Serum Copper/Zinc ratio correlate with Psoriasis Area Severity Index (PASI) and can be used as marker for assessing severity of disease.

Key Words: Psoriasis, Oxidative Stress, trace elements Zinc, Copper.

INTRODUCTION
Psoriasis is a hyper proliferative cutaneous disease of multifactorial etiologies: genetic background, environmental factors, vascular and immune system disturbances. Typical psoriatic lesions are erythematous papules which form plaques characterized by sharp borders and increased scaling.

Oxidative stress, Trace metals and Psoriasis
Oxidative stress has been implicated in the etiopathology of psoriasis. Significant abnormalities of antioxidant mechanisms have been demonstrated in the blood and plaques of psoriatic patients. An insufficient antioxidant system, together with increased levels of reactive oxygen species (ROS) has been suggested to be important in the pathogenesis of this disease. Oxidative stress can result from deficiency of trace elements such as zinc, copper and selenium. The process of keratinization and melanin formation is enzyme-dependent and therefore influenced by Copper and Zinc deficiencies or excesses as trace elements are involved in enzymatic activities and immunologic reactions.

There is no comprehensive study on the levels of trace elements, oxidants and antioxidants defense mechanism and their inter-element relationships in psoriasis. In the present study, Serum Copper and Serum Zinc of Psoriasis patients were analyzed and Serum Copper and Zinc (Cu/Zn) ratio was calculated.

Role of Copper and Zinc in Psoriasis
Copper is associated with a number of mettalloproteins. Copper containing mettaloenzyme superoxide dismutase protects against random free radical damage. Both intracellular and extracellular SODs are copper and zinc containing enzymes, convert super oxide radical to peroxide, which can be removed subsequently by Catalase and other antioxidant defences. The plasma protein ceruloplasmin bind to copper ions and prevents oxidative damage from free copper ions, which generate hydroxyl radicals.

Zn is second to iron as the most abundant trace element in the body. More than 300
metalloenzyme occurs in all six categories of enzyme systems. In some enzymes, such as Cu and Zn superoxide dismutase, structural stability is ensured by zinc protein binding and catalytic activity of the enzyme by the active copper site. Sign and symptom of the zinc deficiency include growth retardation with stunting; increased incident of infection, possibly related to alteration in immune function; diarrhea; reproductive teratogenesis; skin lesions; alopecia; eyesight defect and other adverse clinical outcomes.

One the most common trace metal imbalances are elevated copper and depressed zinc. The ratio of copper to zinc is clinically more important than the concentration of the either of these trace metals. More than the concentration of Zn or Cu in the blood serum, it is more important the balance between them. The optimal plasma or serum ratio between these two elements is 0.70-1.00.

**Aims and Objective**

To study serum COPPER/ZINC (Cu/Zn) ratio as marker of severity of Psoriasis. To estimate serum COPPER/ZINC ratio in Psoriasis patients and in Control groups. To correlate the values of serum COPPER/ZINC (Cu/Zn) ratio with the severity of Psoriasis.

**MATERIAL AND METHOD**

Present study was carried out, at Clinical Chemistry Laboratory in S.S.G. Hospital and Medical College, Vadodara, to measure the level of Serum Copper, Serum Zinc and Serum Copper/Zinc ratio in patient with Mild and Severe Psoriasis after approved by Institutional Ethics Committee for Human Research (IECHR), Medical College and SSG Hospital Baroda, Gujarat, India

EC Reg.no.: ECR/85/Inst/GJ/2013

This case control study consisted of 100 subjects; 50 were patients with Psoriasis attending Skin & V.D. Department, S.S.G. Hospital and Medical College, Vadodara and 50 age and sex matched healthy controls were evaluated. They are divided in two groups depend upon Psoriasis Area and Severity Index score (PASI SCORE)

**Group I (n=20)** consist of patients with PASI SCORE <10 (13 males and 7 females) and **Group II (n=30)** consist of patients with PASI SCORE >10 (20 males and 10 females) and the rest 50 were controls (Group III). Patients and controls with diabetes mellitus, thyroid disease, autoimmune disorder or concomitant dermatological diseases, or had taken systemic or topical treatment within three months before the present study, or receiving any medication that could change serum levels of trace elements such as diuretics, psychologic drugs, anti-arrhythmic medications or supplements were excluded. All patients provided written informed consent.

**Sample**

Fasting blood specimens were taken in the morning between 9-12 hours in the collection Centre OPD. The blood was collected in a plain tube and allowed to clot at room temperature for 30 minutes and centrifuged for 10 minutes at 3500rpm. All the precautions were taken in accordance with the Clinical and Laboratory Standards Institute criteria. To eliminate metal contamination while collecting and storing the samples and samples with signs of hemolysis were discarded.

At the same time, the psoriasis area and severity index (PASI) scores of psoriatic patients were recorded as determined by a Dermatologist.

The serum was divided into proper aliquots and frozen at -20°C until used for measuring of Zn and Cu. Serum Zn and Cu concentrations were estimated by Colorimetric method (Coral Clinical Diagnostic system) in fully Automated Biochemistry Analyzer (Miura 300) at 578 nm. Standard Calibration graph was prepared using working Copper Standard concentrations in the range of 25–200 μg/dl for Cu and Zn.

**Statistical analysis**

All data were given as mean±standard deviation (SD). Statistical software Medcalc used for statistical analysis. Levels of Zn, Cu in sera of patients and control subjects were compared by paired t-test. The differences were considered to be significant when the p value was less than 0.05.
RESULT
This case control study consisted of 100 subjects; 50 were patients with Psoriasis (age ranges: 25-60 years with mean age 42.22±12.0) including 33 males (66%) and 17 females (34%) and 50 controls (age ranges: 25-50 year with a mean age 32.5 ±8.3) including 32 males (64%) and 18 females (36%) were evaluated. (Table 1)
Table 2 show the mean values of trace elements (Zn and Cu), in both patients and controls.
Mean value of Serum Copper in Severe Psoriasis is significantly high (121.29 ± 42.75 µg/dl) compared to Controls (99.9 ± 23.1 µg/dl), which was significant (p<0.005). Mean value of Serum Zinc in Severe Psoriasis is significantly low (66.38 ± 24.33 µg/dl) compared to Controls (82.4 ± 15.9 µg/dl) which was significant (p<0.005). Mean value of Serum Copper/Zinc ratio in Severe Psoriasis is significantly high (2.04 ± 1.04) compared to Mild Psoriasis (1.54 ± 0.71) and Controls (1.02 ± 0.3 µg/dl) which was significant (p<0.005).
Comparison of the values according to the type of psoriasis (Mild and Severe); we found no significant differences for all values studied.

DISCUSSION
Trace elements were measured in order to illuminate the possible role in the pathogenesis of psoriasis. This study was conducted on 50 patients with psoriasis of different severity and 50 healthy volunteer. On measurement of serum trace elements it was found many abnormalities in dermis compared to healthy dermis. The finding of present study indicates that patients with severe psoriasis have higher mean Serum Copper, lower mean Serum Zinc and higher mean Serum Copper/Zinc ratio than with mild psoriasis and controls. Serum levels of trace elements and Cu/Zn were compared against the PASI score and duration of the disease, the serum level of Cu/Zn ratio showed a statistically significant correlation with the PASI score. McMillan et al, reported that psoriatic patients with more extensive skin involvement had lower Zn levels than those with minimal involvement.
Our results indicated that there was no statically significant difference between serum levels of Zn in psoriasis patients with mild and severe disease, while the Cu/Zn ratio was significantly higher in patients. Some investigators have reported increased Zn concentrations in psoriasis scales, serum, urine and uninvolved skin of psoriasis patients. This explained by that zinc used in rapid turnover of the skin and loss of zinc through exfoliation. And zinc deficiency may be the original cause of psoriasis. Some studies noted that psoriatic lesions retain a high content of zinc compared with the uninvolved skin, suggesting an imbalance in zinc distribution between serum and psoriatic lesions. In fact zinc is a co-factor for DNA- and RNA polymerases required for protein synthesis in involved skin. Lowered level of serum protein or albumin which results from peeling off of a large quantity of scales from the body surface, may be also attributable to decreasing zinc level. The unique process of keratinization and melanin formation is enzyme-dependent and therefore could be influenced by trace element deficiencies or excesses as trace elements are involved in enzymatic activities and immunologic reactions.
Basavaraj et al, found decreased Zn concentrations in both mild and severe psoriasis patients consistent with some studies and increased Cu concentrations in both mild and severe psoriasis groups. These inconsistent results may arise from different study designs. Our study was limited to a small number of the patients and many studies are needed on a larger numbers of patients to prove the role of trace elements in the pathogenesis of psoriasis.

CONCLUSION
Serum Copper/Zinc ratio correlate with Psoriasis Area Severity Index (PASI) and can be used as marker for assessing severity of disease. Serum Copper/Zinc ratio is the better marker for assessing severity of the psoriasis than Serum Copper and Zinc alone. Correction of trace...
elements imbalance may help in treatment and outcome of Psoriasis

This table shows that Serum Cu/Zn ratio is significantly high in Psoriasis patients with (group I and II) than Controls (group III) (P<0.05).

Chart: 1 Comparison of Serum Copper and Serum Zinc in all three groups.

This graph shows that Serum Copper is significantly high in patients with severe Psoriasis (group II) than in control (group III). Serum Zn is significantly low in patients with severe Psoriasis (group II) than in control (group III).

Chart: 2 Correlation between Serum Copper/Zinc ratio and PASI SCORE

N=50, r=0.2131

Weak positive correlation, larger population required to achieve statistically significant
