ABSTRACT:

CONTEXT: Coronoid process of mandible is of clinically important maxillofacial surgeons for reconstruction of craniofacial region following trauma, deformities, facial palsy, ankylosis of joints. It also play role as anthropological marker for detection of races. Knowing all the importance the shape of the coronoid processes of both sides of 140 adult human mandibles of which 99 male and 41 female of indian origin were studied in order to classify the variations. STUDY TYPE: Cross-sectional, descriptive type. Place and period of study: Department of anatomy, B.J. Medical college, Ahmedabad-16 from August 2013 to November 2015. MATERIALS AND METHODS: Total 140 human adult mandibles were collected from the Anatomy department of B.J. Medical college, Ahmedabad in the different times of the study period. The study was conducted to observed the variations in the shapes of the coronoid processes. Then their photograps were taken. RESULT: Three types were revealed: 1. Hook shaped; 2. Triangular shaped and 3. Rounded shaped. Hook shaped coronoid processes were found in 126 (45%), triangular in 83 (29.65%) and rounded in 71 (25.35%) sides. Hook shaped coronoid processes were found bilaterally in 56, triangular in 38 and rounded in 30 mandibles. Of the remaining 16 mandibles, the shapes were different on both the sides. The incidence of hook type was almost equal in male and female mandibles, in the triangular type slightly more was found in the female mandibles while the rounded shaped type was more in the male mandibles.

Keywords: Coronoid process, mandible.

INTRODUCTION

The coronoid process of the mandible projects upward and slightly forward as a triangular plate of bone¹. Its margins and medial surface give attachments to temporalis muscle. The coronoid process is of clinical significance to the maxillofacial surgeons for reconstructive purposes. This study was undertaken to MATERIALS AND METHODS collected from the Anatomy department of B.J. Medical College, Ahmedabad in the

The study was (280 sides, 198 males and 82 females) of different times of the study period to observed the variation in the shapes of coronoid processes. The variations of the coronoid processes were observed and their photograps were taken for documentation. Indian origin. The mandibles were note the form of presentations and their prevalence in dry adult human mandibles.

**Shapes of coronoid processes**

There were three types of coronoid process: 1. Hook shaped, 2. Triangular and 3. Rounded shaped (Table-I) were observed among the mandibles. The hook shaped coronoid process had a tip which was pointing backward. This was present in 126 (45%) sides. It was present bilateral in 56 mandibles (112 sides) while in 14 mandibles (9 right, 5 left) it was present unilaterally. Of the 9 right sided mandibles having hook shaped coronoid process, 7 were associated with a rounded and 2 were associated with a triangular coronoid process on the left side. Of the 5 left sided mandibles having hook shaped coronoid process, 3 were associated with a triangular and 2 were associated with a rounded coronoid process on the right side. The triangular coronoid process with a tip pointing straight upward was seen in 83 (29.65%) sides. It was present bilaterally in 38 mandibles (76 sides), while in 7 mandibles (5 right, 2 left), it was found unilaterally. Of the 5 right sided mandibles having triangular coronoid process, 3 were associated with a hook shaped and 2 were associated with rounded coronoid process on the left side. Of the 2 left sided mandibles having triangular coronoid process, both were associated with a hook shaped coronoid process on the right side. The coronoid process with rounded tip was present in 71 (23.35%) sides. In 60 mandibles, (120 sides), rounded coronoid process was present bilaterally, while 11 mandibles (2 right, 9 left), it was found unilaterally. Of the 2 right sided mandibles having rounded coronoid process, both were associated with a triangular coronoid process on the left side. Of the 9 left sided mandibles having rounded coronoid process, 7 were associated with a hook shaped coronoid process and 2 were associated with a triangular coronoid process on the right side. **Distribution of various types in male female mandibles**

The distribution and incidence of the various types of coronoid process were noted in male and female mandibles (Table-II). Of the 198 sides of mandibles belonging to males, the hook shaped type was found in 89 (44.12%), triangular in 54 (27.27%) and rounded in (27.78%). Of the 82 sides of female mandibles, the hook shaped type was found in 37 (45.12%), triangular in 29 (35.37%) and rounded in 16 (19.51%). In this study in 88.57% mandibles the type of coronoid process was the same bilaterally and only in 11.43% mandibles did the presentation differ between sides. The hook shaped and triangular types were the most and least prevalent in males (44.95% and 27.27% respectively). While in females the hook shaped (45.12%) and rounded (19.51%) types were the most and the least prevalent.
Variations in the Shape of the Coronoid Process in the Adult Human Mandible

DISCUSSION

The coronoid process, coronoid meanin ‘crow’ ha been described as one of the bony processes of the ramus of the mandible. Standing et al, described the coronoid process as a flat triangular process. Triangular process have been illustrated by Hamilton, Romanes, Snell and Basmajian et al. Schafer et al, described the coronoid process as beak-shaped. Knowledge of the morphological shapes of the coronoid process is useful for the maxillofacial surgeons. The coronoid process makes an excellent donor graft site for reconstruction of orbital floor deformities. Clauser et al, reported the use of a temporalis myofascial flap both as a single and as craniomaxillofacial surgery including trauma, deformities, tumors, temporomandibular joint ankylosis and facial paralysis. To our knowledge this is the first study to identify and classify the different morphological shapes of the coronoid process in Indian mandible. Along with other features of the skull known as nonmetric variants these could be used as anthropological markers to assess different populations and races.
